The recovery factor of horizontal wells ranges from less than 10% up to around 50% with the average at around mid-20%. This is a significant improvement from the recovery factor of deviated wells; the average is around 10%.

increase in oil recovery rate is the presence of zones with high vertical permeability (e.g. the faults and fault-related fractures mentioned above). However, with advance planning, these can be dealt with using selective completion techniques. Horizontal wells remove oil from a reservoir over a long producing zone at relatively slow rates. In contrast, vertical wells take oil very quickly ...

horizontal wells from primary recovery to EOR applications. The paper includes field examples of different applications. . Although horizontal wells have been drilled as early as 1927, the major thrust of drilling horizontal wells started in 1980. Initial wells were short length wells (about 250 ft. long wells). In 1985, the first medium radius horizontal well was drilled using a down-hole mud ...

oil (3.7% recovery factor). Currently, the oil production rate is 180.3 thousand BOPD, of which 159.6 thousand BOPD (88.5%) come from horizontal wells. The actual operator company has implemented an aggressive campaign, drilling over 296 horizontal wells from 2006 to 2011. Since 1981, 202 vertical wells and 7 deviated wells have been drilled. In Areniscas Basales Unit, the average production ...

Oil Sands Recovery - Production Technologies. VAPEX (Vapor Extraction Process) The VAPEX process is a technology similar to SAGD but instead of steam, solvent is injected into the oil sands resulting in significant viscosity reduction. The injection of vaporized solvents such as ethane or propane help create a vapor-chamber through which the oil flows due to gravity drainage. The process can ...

drilling of horizontal wells would likely be financial folly, since a vertical well program could achieve a similar recovery of oil at lower cost. But when low matrix permeability exists in Figure 1. With SAGD, pairs of horizontal wells are drilled into the producing zone, one about five metres above the other. Steam injected into the top well heats the formation and reduces the viscosity of oil around the wellbore. Gravity then pushes the warm oil toward the producing well below. Since steam generation is the largest single expense, the trick with SAGD or any steam process is to minimize ...

Horizontal drilling was originally developed by industry for oil recovery, utility placement, mining, and construction dewatering. It was modified for the environmental remediation industry in the late 1980s and early 1990s. Over 1,000 horizontal wells have been cataloged as of December 31, 1999. Wells have been completed to over a thousand feet in length.
